

DESCRIPTIVE ABSTRACT

The object of the invention is a process for the qualitative and quantitative detection of damage in DNA,
5 comprising the following different steps:

- preparation of DNA,
 - damaging treatment of this DNA, and
 - securement of this damaged DNA to a sensitized solid support, or
 - 10 - preparation of DNA,
 - securement of this undamaged DNA on a sensitized solid support, and
 - damaging treatment of the DNA, or
 - treatment of cells,
 - 15 - lysis and capture of cellular DNA,
- characterized in that it consists in:
- causing to act on this damaged DNA a composition comprising at least one cellular extract or a purified protein having at least one activity for recognizing and/or repairing damage, and
 - 20 - detecting on the damaged DNA, directly or indirectly, the presence of recognition and/or repair proteins of the damage produced,

- all the steps being separated by at least one washing step.

The invention also relates to the materials for practicing this process.
